GB/T 6682—1992 Water for analytical laboratory use—Specification and test methods (neq ISO 3696)

3 Method abstract

After the sample is cleared up with nitric acid in microwave devices, lead, cadmium, arsenic, and mercury contained in it. After reaction with potassium borohydride, lead and arsenic introduce volatile hydride, mercury introduces Hg vapour, and cadmium introduces volatile matter of cadmium. These products are carried into quartz atomizer through argon gas respectively. Under the irradiation of specially configured hollow cathode lamp, it emits fluorescence with characteristic wavelength. The fluorescence intensity is directly proportional to the content of elements determined, and quantified after the comparison with standard series.
